Notes

From an email: " While skinning...we felt many large collapses in shallow, wind-affected snow. On the ridge crest, we found a ~3cm crust on the surface with massive (~6mm+), striated facets underneath. After skiing down an east-facing, 400', low angle slope, we felt a large [collapse](#) that traveled at least 60 feet, but continued rumbling for several seconds and may have propagated back up the slope that we skied. The [collapse](#) was triggered in shallow snow in the flats. This weak snow structure near the surface was not present in the next drainage east."
